# Abstract

**Background** One of the most challenging problems in developing countries including Ethiopia is improving maternal health. About 303,000 mothers die globally, and one in every 180 is at risk from maternal causes. Developing regions account for 99% of maternal deaths. Maternal near miss (MNM) resulted in long-term consequences. A systematic review and meta-analysis was performed to assess the prevalence and predictors of maternal near miss in Ethiopia from January 2015 to March 2023.

**Methods** A systematic review and meta-analysis cover both published and unpublished studies from different databases (PubMed, CINHAL, Scopus, Science Direct, and the Cochrane Library) to search for published studies whilst searches for unpublished studies were conducted using Google Scholar and Google searches. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines were used. Duplicated studies were removed using Endnote X8. The paper quality was also assessed based on the JBI checklist. Finally, 21 studies were included in the study. Data synthesis and statistical analysis were conducted using STATA Version 17 software. Forest plots were used to present the pooled prevalence using the random effect model. Heterogeneity and publication bias was evaluated using Cochran's Q test, (Q) and I squared test (I<sup>2</sup>). Subgroup analysis based on study region and year of publication was performed.

**Result** From a total of 705 obtained studies, twenty-one studies involving 701,997 pregnant or postpartum mothers were included in the final analysis. The national pooled prevalence of MNM in Ethiopia was 140/1000 [95% CI: 80, 190]. Lack of formal education [AOR=2.10, 95% CI: 1.09, 3.10], Lack of antenatal care [AOR=2.18, 95% CI: 1.33, 3.03], history of cesarean section [AOR=4.07, 95% CI: 2.91, 5.24], anemia [AOR=4.86, 95% CI: 3.24, 6.47], and having chronic medical disorder [AOR=2.41, 95% CI: 1.53, 3.29] were among the predictors of maternal near misses from the pooled estimate.

**Conclusion** The national prevalence of maternal near miss was still substantial. Antenatal care is found to be protective against maternal near miss. Emphasizing antenatal care to prevent anemia and modifying other chronic medical conditions is recommended as prevention strategies. Avoiding primary cesarean section is recommended unless

Finally, the country should place more emphasis on strategies for reducing MNM and its consequences, with the hope of improving women's health.

# Background

Globally, 303 000 mothers die each year from maternal causes, with one in every 180 at risk; developing regions account for 99% of maternal deaths [1]. Millions of women suffered from pregnancy and its complications, including death, and the majority (94%) of these deaths occurred in low- and middle-income countries [2]. Sub-Saharan African countries continue to share the largest portion of maternal mortality [3]; about 66% of global MMR accounts for sub-Saharan Africa alone [4]. However, it is rare in absolute numbers in the community, possibly due to underreporting by healthcare providers and managers [5].

Direct obstetric causes like hemorrhage, hypertensive disorder of pregnancy (pre-eclampsia, eclampsia), postpartum sepsis, obstructed labor, uterine rupture, and abortion-related death are among the most common causes of maternal morbidity and mortality [2, 6, 7].

For every woman who dies from pregnancy or childbirth-related causes, about twenty more experienced maternal near miss [8]. World Health Organization (WHO) defines a maternal near-miss (MNM) as a woman who nearly died but survived a complication that occurred during pregnancy, childbirth, or within 42 days of termination of pregnancy [9, 10].

The national annual incidence of maternal near miss was 7.2 per 1,000 live births in Kenya [11], 22.1 per 1000 live births in Sudan [12], and 23.6 per 1,000 live births in Tanzania [13]. In Uganda, the MNM rate was 287.7/1000 pregnancies [14]. Maternal near miss in Ethiopia ranges from 4.97% to 29.7% [15, 16], one study reported a 50.4 per 1000 live births ratio [17].

Studying MNM is very important, as maternal mortality is more likely to be underreported by healthcare providers and managers, especially in low-income countries [18]. MNM shows the quality of obstetric intervention to save the lives of mothers and also provides the chance of interviewing the mother [19].

All countries must contribute to achieve the global target of MMR of less than 70 per 1,000 live births, and no country should have MMR of more than 140 per 1,000 live births by 2030 [20, 21]. Ethiopia is one of the countries that strive to reduce maternal mortality through different strategies, such as the promotion of maternal health, the provision of free maternity services and the provision of supplies [22]; however maternal mortality remains a public concern [10, 23, 24].

MNM is associated with life-threatening pregnancy outcomes like stillbirth, birth asphyxia, and low birth weight [25–28]. This bad pregnancy outcome can be reduced by identifying predictors, implementing intervention for context-specific quality improvement [29], and addressing modifiable risk factors accordingly [30].

Different predictors that were associated with maternal near misses in Ethiopia include, delay to seek health care, referred from the health facility, history of cesarean Section. [31–33], no formal education [28, 32], travelling greater than 60 min to reach the place of final care [15, 32, 33], induction of labor [15, 32, 33], age less than 16 [32], history of chronic medical disorders [28, 32, 33], lack of ANC [15, 33], lack of birth preparedness and complication readiness plan [33], less monthly income, and rural residence [28].

Understanding the estimated national burden of MNM and its predictors is very important. This will enable policymakers and anyone else who wants to take action to reduce maternal morbidity and mortality to do so based on evidence. Apart from different studies across the countries that are inconsistent and make generalizability difficult, there is a paucity of pooled national evidence on the burden of MNM and its predictors. Therefore, this study aimed to determine the pooled prevalence of maternal near-miss and its determinants among women in Ethiopia by including a study published after 2015, as it was a turning point from millennium development goals to sustainable development goals.

#### Methods

#### Systematic review registration and reporting of findings

The protocol for this study has been registered on the International Prospective Register of Systematic Review (PROSPERO), the University of York Center for Reviews and Dissemination (https://www.crd.york.ac.uk/) with registration number CRD42023393803. The finding of the study was reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA 2020) [34] guidelines.

#### Eligibility criteria and study selection

The systematic review and meta-analysis were designed to determine the magnitude of MNM and its determinants among pregnant and postpartum women in Ethiopia. A maternal near miss is a woman who nearly died but survived a complication that occurred during pregnancy, childbirth or within 42 days of termination of pregnancy [10].

This study included all published studies (cross-sectional, case–control, and cohort) that reported the magnitude and/or determinants of a maternal near-miss in Ethiopia, with full text and written in English. However, studies that only included abstracts, case reports and written in languages other than English were excluded. End note X8 was used to remove the duplicated result. Three authors (AN, ML, TB), screened the article by reading the title and abstract based on predefined inclusion and exclusion criteria.

# Sources and search strategy

The systematic review took into account English-language studies that were published between January 2015 and March 2023. Searches for published research were conducted using electronic databases like PubMed/Medline, Scopus, CINHAL, Science Direct, and the Cochrane Library, whilst searches for unpublished studies were conducted using Google Scholar, Advanced Google Search and Google. Keywords and medical subject heading terms were used to search an electronic data repository. The discovered PECO components were connected using Boolean operators.

The search strategy for advanced PubMed includes: ((((("epidemiology"[Subheading] OR "epidemiology"[All Fields] OR "prevalence"[All Fields] OR "prevalence"[MeSH Terms]) OR determinants[All Fields]) OR burden[All Fields]) AND ("mothers"[MeSH Terms] OR "mothers"[All Fields]) AND (("mothers"[MeSH Terms] OR "mothers"[All Fields]) AND (("mothers"[MeSH Terms] OR "mothers"[All Fields]) OR "maternal"[All Fields]) AND near[All Fields] OR "maternal"[All Fields]) AND near[All Fields] AND miss[All Fields])) AND Ethiopia[Title].

## For scopus search

Aditional searching (ALL (prevalence) AND ALL(maternal AND nearmiss) OR TITLE-ABS-KEY (maternal AND near-miss) AND TITLE-ABS-KEY (predictors) OR ALL (associated AND factors) AND TITLE-ABS-KEY (Ethiopia)) were used. Then all identified keywords and index terms were checked across all databases. Finally the reference lists of all identified articles were searched for further articles.

#### Quality assessment and data extraction

Data extraction was done by five authors (ML, AN, AS, HD and FT) by using an extraction format prepared on Microsoft Excel. The extracted data were first author name, publication year, publication place, study design,

sample size, sampling method, maternal near miss, determinants with odd ratio, and causes that resulted in maternal near miss.

Each screened article was evaluated by five authors (AN, ML, AS, AB, and DA) for quality assurance using standardized critical evaluation tools, Joanna Briggs Institute (JBI) Critical Appraisal tools [35]. Then the quality of each included article was classified as high (80% or above), moderate (65%–80%), or low (less than 65%). The final inclusion was determined by reading the full text of the articles by five authors (AS, EY, KN, Til. B and AT). Finally, the included article was verified by (MD, DA, HF and GD). Any disagreement was resolved by the discussion after the same procedure was repeated.

# **Outcome of interest**

The primary outcome of this systematic review is the magnitude of maternal near miss in Ethiopia. The secondary outcome is determinants of maternal near miss.

#### Statistical analysis and publication bias

Data synthesis and statistical analysis were conducted using STATA version 17. The random effect model of analysis was used as a method of meta-analysis to reduce the heterogeneity of included studies. Subgroup metaanalysis was done by study setting, sample size and year of publication. A forest plot was used to present the result of the meta-analysis. Heterogeneity among included articles was evaluated using Cochran's Q test, (Q) and I squared test ( $I^2$ ).  $I^2$  test statistics of 25%, 50% and 75% were declared as low, moderate and high heterogeneity, respectively. The effect of factors associated with maternal near misses was pooled. The investigators checked for potential publication bias through visual inspection of a funnel plot and Egger's Regression Test. A p-value of less than 0.05 was used as statistical evidence of publication bias. Finally, the findings of the included studies were first presented using a narrative synthesis and followed by a meta-analysis chart.

# Result

#### Study identification

Initially, 705 studies were retrieved from electronic databases like PubMed/Midline, Scopus, CINHAL and Science Direct. Unpublished studies were searched from Google Scholar and advanced Google search and Google. The major reason for exclusion was duplication and mismatch. 105 duplicate was found and removed. 599 studies were screened by title and abstract 541 of them were removed due to mismatch. 58 studies were sought for retrieval and 11 were not retrieved. A full text was assessed for illegibility (English language, report

prevalence of MNM and/or its predictors, present in full text, a study done in Ethiopia after 2015 and moderate and above in quality) and finally, 21 studies were included in a systematic review and meta-analysis (Fig. 1).

### **Study characteristics**

A total of 701,997 pregnant or postpartum mothers who visited the health facility for Obstetrics or Gynecologic services from 21 studies were included. A study published from January 2015 to March 2023 in Ethiopia, of which 5 studies were from the Amhara region, 5 from the Oromia region, 4 studies were from the Southern Nation Nationalities and Peoples (SNNP) region, 1 study from the Harar region, 2 studies from the Tigray region, 3 studies from Addis Abeba city, and another study that was done nationally, were included. Eight of them were published before 2020, while the rest were published after 2020. Regarding the quality

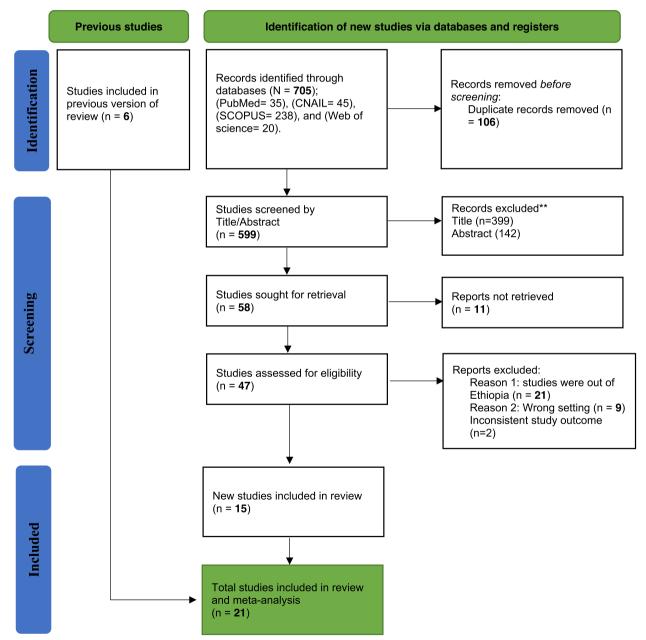

Fig. 1 PRISMA flow diagram of the studies included in final systematic review and meta-analysis of maternal near miss in Ethiopia, 2023 [36]

of included studies 10 were moderate while the rest 11 were high quality based on JBI (Additional file 1). 12 of 22 studies used a cross-sectional study design, while the rest used a case-control, except for one study that used a survey from national data. From the total included studies 8 used record review for data collection, while 12 studies used interviews supported by chart review. The sample size ranges from 296 to 78,195 (Table 1).

# Prevalence of maternal near miss

The pooled prevalence of maternal near misses from 13 studies indicated 14% [95% CI: 8, 19]. Considerable heterogeneity was observed across the included studies [ $I^2$ =99.98, p < 0.001] (Fig. 2).

#### Subgroup analysis

Subgroup analysis based on the study setting (region) didn't show any significant variation. Based on the subgroup analysis result, the highest prevalence (20%, 95% CI: 14, 26)  $I^2 = 99.92\%$ ) was seen in the Amhara region, and the lowest prevalence (3%, 95% CI: 2, 4),  $I^2 = .\%$ ) was seen in the Tigray region (Fig. 3).

There is no significant variation between studies published before and after 2020 (Fig. 4).

### Sensitivity analysis

The result of the sensitivity analysis done by dropping large and small sample sizes alternatively indicated there was no significant difference (Table 2).

# Factors associated with maternal near misses

Nine studies were included to assess the relationship between residence and MNM [31, 32, 36, 38, 43, 47, 49–51]. From the pooled estimate, there is no association between rural residence and maternal near misses [AOR 0.98, 95% CI, 0.66, 1.30]. Ten studies were included to evaluate the association between ANC and MNM [15, 31, 36, 43, 44, 47–51]. From pooled estimates, mothers who have no ANC were 2.18 times more likely to develop MNM when compared to those who have ANC [AOR=2.18, 95% CI: 1.33, 3.03] (Fig. 5).

The association between cesarean section (CS) and maternal near-miss was also assessed by 7 studies [31, 32, 36, 37, 47, 49, 51]. A pooled estimate revealed that a mother who has a history of cesarean section is 4.07 times more likely to develop MNM when compared to those who have no history of CS [AOR=4.07, 95% CI: 2.91, 5.24]. There is no observed heterogeneity ( $I^2=0$ ) (Fig. 6).

Random-effects REML model

Fig. 2 Forest plot indicating a pooled prevalence of maternal near misses in Ethiopia, 2023

Three studies were pooled to assess the association between anemia in index pregnancy and MNM [36, 37, 50]. Those who had anemia were 4.86 times more likely to develop MNM when compared to those who had no anemia [AOR=4.86; 95% CI: 3.24, 6.47]. There is no heterogeneity in the study  $[I^2=0.00\%]$ . The effect of chronic medical disorders on MNM was assessed by a pooled estimate of five studies [32, 37, 47, 49, 51]. Those who have had a history of chronic medical disorders were 2.41 times more likely to develop MNM when compared to their counterparts [AOR = 2.41; 95% CI: 1.53, 3.29]. There is no variability among the included studies  $[I^2 = 0.00\%]$ . Four studies were included to evaluate the effect of educational level on MNM [32, 48, 49, 51]. The pooled estimate indicated that those who have no formal education were 2.10 times more likely to develop MNM when compared to the educated group [AOR=2.10; 95% CI: 1.09, 3.10].

Additionally, factors like grand multiparty, residence, and a delay of 60 min were pooled to look at their effects. Even though those predictors were significantly associated in some studies, the pooled estimate fails to indicate a significant association.

#### Discussion

The prevalence and factors associated with maternal near miss in Ethiopia were assessed and analyzed. From the 21 studies included in this systematic review and metaanalysis, 13 were used to compute the pooled prevalence, while 14 studies were used to assess factors associated with maternal near miss.

The pooled prevalence of maternal near miss from 13 studies (about 378,173 study participants) indicated 14% [95% CI: 8, 19]. This finding was greater than the global weighted pooled burden of maternal near misses [52], a study done in sub-Saharan Africa, Europe and Northern America [53], a study done in Tanzania [13], Latin America [54], Kenya [11], Harare, Namibia [55], Zimbabwe [56], South Africa [57], Eastern India [58] and Rwanda [59]. The reason for this variation could be the scope of the study, the year of publication, and the nature of the variation of MNM among high and low-income countries.

This finding is consistent with a systematic review and meta-analysis conducted in Ethiopia [19], a study conducted in Rwanda [60], Ghana [61], Indonesia and Western Pacific [62]. This could be because they belong

Fig. 6 Association between history cesarean section and maternal near miss in Ethiopia 2023

the difference in socio-demographics and health care systems of the study population.

In this meta-analysis, women who lack ANC follow-up were more likely to have maternal near miss. This finding was supported by a systematic review and meta-analysis (SRMA) in Ethiopia [19, 64]. This could be because lack of ANC is many things in obstetrics. It is a lack of screening, diagnosis and management, supplementation, health education [65] and a lack of birth preparedness complication readiness plan which resulted in poor pregnancy outcomes [66]. Also, those who have a history of cesarean section (CS) were 4.07 times more likely to have MNM. This finding was supported by a systematic review and meta-analysis study [67]. This is because the presence of a uterine scar could be one factor in the occurrence of complications like uterine rupture and hemorrhage [68]. Additionally, different complications can occur intraoperatively and can result in maternal near miss.

Another predictor was anemia, which increased 4.86 times the odds of having MNM among those who have anemia when compared to those who do not have anemia. Furthermore, those who had chronic medical disorders were 2.41 times more likely to have MNM when compared to their counterparts. This could be because medical disorders, including anemia, can be exacerbated by the physiologic nature of pregnancy and contribute to maternal MNM [69-72]. Educational status is another factor that affects maternal near miss. From the pooled estimate, participants who have no formal education were 2.10 times more likely to develop MNM when compared to the educated group. This could be because uneducated women may be less knowledgeable, limited awareness of their health and pregnancy danger signs, and are less likely to utilise maternity healthcare services [73-77].

This finding has considerable heterogeneity and should be interpreted with some limitations. The highest heterogeneity may be explained by the difference in study design or characteristics of the study population.

# Conclusion

The national prevalence of maternal near misses was still substantial. Lack of formal education, lack of ANC, history of cesarean section, anemia, and chronic medical disorders were among the predictors of maternal near miss. Antenatal care is found to be a special opportunity and area to intervene. More ANC contact as recommended by WHO should be practised. Avoiding primary cesarean section is recommended unless a clear indication is present. The country should give more emphasis on strategies for reducing MNM and its consequence, with the hope of improving women's health.

#### Strengths and limitations of the study

The study provided pooled prevalence of maternal near misses which is more representative than a single study and is strong evidence. There is considerable heterogeneity across the study. This could be due to different study populations, study designs, data collection methods and sample sizes. Also, the funnel plot is asymmetric indicating publication bias, as any significant finding with maternal near-miss is more likely to be published. Therefore the interpretation of the finding should be cautious.

#### Authors' contributions

Abraham Negash is a principal investigator. All authors contributed to the work equally whether it is at conception (A.N, ML), screening (AN, ML, TB), evaluation of finally included article (AS, EY, KN, Til. B and AT), verification of included article (MD, HF and GD), data extraction (ML, AN, AS, HD and FT), evaluation for quality assurance (AN, AS, and DA). Analysis (AN, DA and AB), and drafting (AN, DB and ML). All authors participated in critically reviewing the final draft and agreed to be accountable for all aspects of the work.

#### Funding

This study received no specific financing from governmental, private, or nonprofit funding bodies.

#### Availability of data and materials

Additional data can be available from the corresponding author upon reasonable request.

#### Declarations

#### Ethics approval and consent to participate

The study was carried out following relevant guidelines and regulations of the Helsinki Declaration of medical research ethics as it included ethically approved articles only. Ethical approval for each included individual article works for this systematic review and meta-analysis.

#### **Consent for publication**

Not Applicable.

## **Competing interests**

The authors declare no competing interests.
